

### **Functions and Lambdas**

How can we make template functions even more general?

CS106L - Spring 23

# Attendance! <a href="https://bit.ly/44knqp8">https://bit.ly/44knqp8</a>

http://web.stanford.edu/class/cs106l/

#### **Announcements!**

- No class **next week** midquarter break!
  - Office hours during class time (3-4:30pm)
  - Review material from the lectures so far!
- After this lecture, you will be able to complete Assignment 1!
  - Due May 12th!

#### **CONTENTS**

**02.** Functions and Lambdas Passing input outside of parameters

**03.** Algorithms

#### **CONTENTS**

**02.** Functions and Lambdas

Passing input outside of parameters

**03.** Algorithms

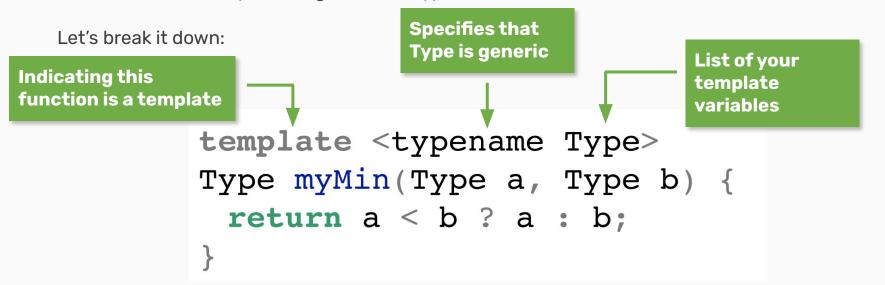

# Template functions are completely generic functions!

Just like classes, they work regardless of type!

# **Calling template functions**

We can **explicitly** define what type we will pass, like this:

```
template <typename Type>
Type myMin(Type a, Type b) {
  return a < b ? a : b;
}

// int main() {} will be omitted from future examples
// we'll instead show the code that'd go inside it
cout << myMin<int>(3, 4) << endl; // 3</pre>
Just like in
template classes!
```

# **Calling template functions**

We can also **implicitly** leave it for the compiler to deduce!

```
template <typename T, typename U>
auto smarterMyMin(T a, U b) {
  return a < b ? a : b;
}

// int main() {} will be omitted from future examples
// we'll instead show the code that'd go inside it
cout << myMin(3.2, 4) << endl; // 3.2</pre>
```

# **Review: Template Functions**

- Template functions allow you to parametrize the type of a function to be anything without changing functionality
- Generic programming can solve a complicated conceptual problem for any specifics – powerful and flexible!
- Template code is instantiated at compile time;
   template metaprogramming takes advantage of this to
   run code at compile time

#### **CONTENTS**

http://web.stanford.edu/class/cs106l/

# Let's review that count\_occurrences function!

This code will work for any containers with any types, for a single specific target.

```
template <typename InputIt, typename DataType>
int count_occurrences(InputIt begin, InputIt end, DataType val) {
   int count = 0;
   for (auto iter = begin; iter != end; ++iter) {
      if (*iter == val) count++;
    }
   return count;
}

Usage: std::string str = "Xadia";
   count_occurrences(str.begin(), str.end(), 'a');
```

This code will work for any containers with any types, for a single specific target.

Will this work for a more general category of targets than one specific value?

```
template <typename InputIt, typename DataType>
int count_occurrences(InputIt begin, InputIt end, DataType val) {
   int count = 0;
   for (auto iter = begin; iter != end; ++iter) {
      if (*iter == val) count++;
    }
   return count;
}

Usage: std::string str = "Xadia";
   count_occurrences(str.begin(), str.end(), 'a');
```

This code will work for any containers with any types, for a single specific target.

Will this work for a more general category of targets than one specific value?

```
template <typename InputIt, typename DataType>
int count_occurrences(InputIt begin, InputIt end, DataType val) {
   int count = 0;
   for (auto iter = begin; iter != end; ++iter) {
      if (*iter == val) count++;
   }
   return count;
}

Usage: std::string str = "Xadia";
   count_occurrences(str.begin(), str.end(), 'a');
Wha
```

What if we wanted to find all the vowels in "Xadia"?

This code will work for any containers with any types, for a single specific target.

Will this work for a more general category of targets than one specific value?

```
template <typename InputIt, typename DataType>
int count_occurrences(InputIt begin, InputIt end, DataType val) {
   int count = 0;
   for (auto_iter = begin; iter != end; ++iter) {
      if (*iter == val) count++;
   }
   return count;
}

Usage: std::string str = "Xadia";
   count_occurrences(str.begin(), str.end(), 'a');
```

This code will work for any containers with any types, for a single specific target.

Will this work for a more general category of targets than one specific value?

```
template <typename InputIt, typename DataType>
int count_occurrences(InputIt begin, InputIt end, DataType val) {
   int count = 0;
   for (aute iter = begin; iter != end;
        if (*iter == val) count++;
   }
   return count;
}

Usage: std::string str = "Xadia";
   count_occurrences(str.begin(), str.end(), 'a');
```

Any function that returns a boolean value is a predicate!

Any function that returns a boolean value is a predicate!

 isVowel() is an example of a predicate, but there are tons of others we might want!

Any function that returns a boolean value is a predicate!

 isVowel() is an example of a predicate, but there are tons of others we might want!

```
bool isLowercaseA(char c) {
    return c == 'a';
}

bool isVowel(char c) {
    std::string vowels = "aeiou";
    return vowels.find(c) != std::string::npos;
}
```

```
bool isMoreThan(int num, int limit) {
    return num > limit;
}
bool isDivisibleBy(int a, int b) {
    return (a % b == 0);
}
```

Any function that returns a boolean value is a predicate!

- isVowel() is an example of a predicate, but there are tons of others we might want!
- A predicate can have any amount of parameters...

```
bool isLowercaseA(char c) {
    return c == 'a';
}

bool isVowel(char c) {
    std::string vowels = "aeiou";
    return vowels.find(c) != std::string::npos;
}
```

```
bool isMoreThan(int num, int limit) {
    return num > limit;
}
bool isDivisibleBy(int a, int b) {
    return (a % b == 0);
}
```

Any function that returns a boolean value is a predicate!

- isVowel() is an example of a predicate, but there are tons of others we might want!
- A predicate can have any amount of parameters...

#### **Unary**

```
bool isLowercaseA(char c) {
    return c == 'a';
}

bool isVowel(char c) {
    std::string vowels = "aeiou";
    return vowels.find(c) != std::string::npos;
```

#### **Binary**

```
bool isMoreThan(int num, int limit) {
    return num > limit;
}
bool isDivisibleBy(int a, int b) {
    return (a % b == 0);
}
```

```
template <typename InputIt, typename DataType, typename UniPred>
int count occurrences(InputIt begin, InputIt end, UniPred pred) {
    int count = 0;
    for (auto iter = begin; iter != end; ++iter) {
        if (*iter == val pred(*iter)) count++;
   return count;
bool isVowel(char c) {
    std::string vowels = "aeiou";
   return vowels.find(c) != std::string::npos;
Usage: std::string str = "Xadia";
      count occurrences(str.begin(), str.end(), isVowel);
```

```
template <typename InputIt, typename DataType, typename UniPred>
int count occurrences (InputIt begin, InputIt end, UniPred pred) {
    int count = 0;
    for (auto iter = begin: iter != end: ++iter) {
        if (*iter == val pred(*iter)) count++;
   return count;
bool isVowel(char c) {
    std::string vowels = "aeiou";
   return vowels.find(c) != std::string::npos;
Usage: std::string str = "Xadia";
      count occurrences(str.begin(), str.end(), isVowel);
```

```
template <typename InputIt, typename DataType, typename UniPred>
int count_occurrences(InputIt begin, InputIt end, UniPred pred)
    int count = 0;
    for (auto iter = begin; iter != end; ++iter) {
        if (*iter == val pred(*iter)) count++;
   return count;
bool isVowel(char c) {
    std::string vowels = "aeiou";
   return vowels.find(c) != std::string::npos;
Usage: std::string str = "Xadia";
      count occurrences(str.begin(), str.end(), isVowel);
```

```
template <typename InputIt, typename DataType, typename UniPred>
int count_occurrences(InputIt begin, InputIt end, UniPred pred)
    int count = 0;
    for (auto iter = begin; iter != end; ++iter) {
        if (*iter == val pred(*iter)) count++;
   return count;
                                                        What type is UniPred???
bool isVowel(char c) {
    std::string vowels = "aeiou";
   return vowels.find(c) != std::string::npos;
Usage: std::string str = "Xadia";
      count occurrences(str.begin(), str.end(), isVowel);
```

http://web.stanford.edu/class/cs106l/

#### **Function Pointers**

UniPred is what's called a **function pointer!** 

http://web.stanford.edu/class/cs106l/

#### **Function Pointers**

UniPred is what's called a function pointer!

Function pointers can be treated just like other pointers

#### **Function Pointers**

UniPred is what's called a function pointer!

- Function pointers can be treated just like other pointers
- They can be passed around like variables as parameters or in template functions!

http://web.stanford.edu/class/cs106l/

#### **Function Pointers**

UniPred is what's called a function pointer!

- Function pointers can be treated just like other pointers
- They can be passed around like variables as parameters or in template functions!
- They can be called like functions!

# Is this good enough?

Are there any ways this could be an issue?

```
template <typename InputIt, typename DataType, typename UniPred>
int count occurrences(InputIt begin, InputIt end, UniPred pred) {
    int count = 0;
    for (auto iter = begin; iter != end; ++iter) {
        if (*iter == val pred(*iter)) count++;
    return count;
bool isVowel(char c) {
    std::string vowels = "aeiou";
    return vowels.find(c) != std::string::npos;
Usage: std::string str = "Xadia";
      count occurrences(str.begin(), str.end(), isVowel);
```

http://web.stanford.edu/class/cs106l/

#### **Poor Generalization**

Unary predicates are pretty limited and don't generalize well.

```
bool isMoreThan3(int num) {
    return num > 3;
bool isMoreThan4(int num) {
    return num > 4;
bool isMoreThan5(int num) {
    return num > 5;
```

#### **Poor Generalization**

Unary predicates are pretty limited and don't generalize well.

Ideally, we'd like something like this!

```
bool isMoreThan3(int num) {
    return num > 3;
bool isMoreThan4(int num) {
    return num > 4;
bool isMoreThan5(int num) {
    return num > 5;
// a generalized version of the above
bool isMoreThan(int num, int limit) {
    return num > limit;
```

# Can we use binary predicates?

If we could, it would be nice to use a binary predicate to handle this!

```
template <typename InputIt, typename BinPred>
int count_occurrences(InputIt begin, InputIt end, BinPred pred) {
   int count = 0;
   for (auto iter = begin; iter != end; ++iter) {
      if (pred(*iter, ???)) count++;
   }
   return count;
}
```

# Can we use binary predicates?

How do we know what value to use? What about unary (or any other number of arguments) predicates?

```
template <typename InputIt, typename BinPred>
int count_occurrences(InputIt begin, InputIt end, BinPred pred) {
   int count = 0;
   for (auto iter = begin; iter != end; ++iter) {
      if (pred(*iter, ???)) count++;
   }
   We can't pass this in from the predicate!
}
```

count occurrences(str.begin(), str.end(), isVowel);

#### The Catch-22

We want our function to know more information about our predicate.

#### The Catch-22

We want our function to know more information about our predicate.

However, we can't pass in more than one parameter.

#### The Catch-22

We want our function to know more information about our predicate.

However, we can't pass in more than one parameter.

How can we pass along information without needing another parameter?

Lambdas are inline, anonymous functions that can know about functions declared in their same scope!

```
auto var = [capture-clause] (auto param) -> bool
{
    ...
}
```

Lambdas are **inline**, anonymous functions that can know about variables declared in their same scope!

```
auto var = [capture-clause] (auto param) -> bool
```

Lambdas are inline, **anonymous** functions that can know about variables declared in their same scope!

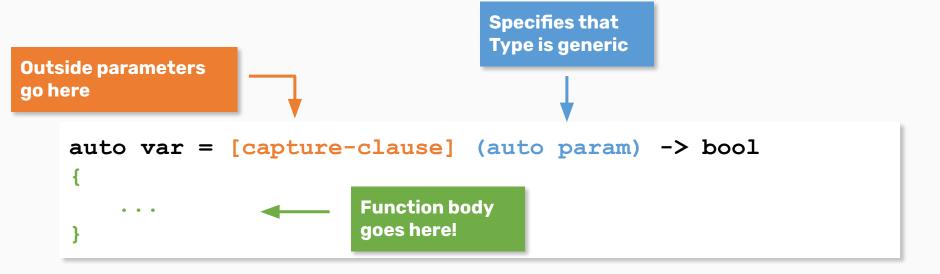

```
auto var = [capture-clause] (auto param) -> bool
```

Lambdas are inline, **anonymous** functions that can know about variables declared in their same scope!

It might look something like this!

```
int limit = 5;
auto isMoreThan = [limit] (int n) { return n > limit; };
isMoreThan(6); // true
```

It might look something like this!

```
int limit = 5;
auto isMoreThan = [limit] (int n) { return n > limit; };
isMoreThan(6); // true
```

### **Capture Clauses**

You can capture any outside variable, both by reference and by value.

### **Capture Clauses**

You can capture any outside variable, both by reference and by value.

Use just the = symbol to capture everything by value,
 and just the & symbol to capture everything by
 reference

### We've solved our problem!

```
template <typename InputIt, typename UniPred>
int count_occurrences(InputIt begin, InputIt end, UniPred pred) {
    int count = 0;
    for (auto iter = begin; iter != end; ++iter) {
        if (pred(*iter)) count++;
   return count;
Usage:
int limit = 5;
auto isMoreThan = [limit] (int n) { return n > limit; };
std::vector<int> nums = {3, 5, 6, 7, 9, 13};
count occurrences(nums.begin(), nums.end(), isMoreThan);
```

### We've solved our problem!

```
template <typename InputIt, typename UniPred>
int count_occurrences(InputIt begin, InputIt end, UniPred pred) {
   int count = 0;
   for (auto iter = begin; iter != end; ++iter) {
      if (pred(*iter)) count++;
   }
   return count;
}
Usage:
int limit = 5;
auto isMoreThan = [limit] (int n) { return n > limit; };
std::vector<int> nums = {3, 5, 6, 7, 9, 13};
count_occurrences(nums.begin(), nums.end(), isMoreThan);
```

### **Using Lambdas**

Lambdas are pretty computationally cheap and a great tool!

- Use a lambda when you need a short function or to access local variables in your function.
- If you need more logic or overloading, use function pointers.

# Let's do some practice!

A **functor** is any class that provides an implementation of operator().

```
class functor {
public:
    int operator() (int arg) const { // parameters and function body
        return num + arg;
    }
private:
    int num; // capture clause
};
int num = 0;
auto lambda = [&num] (int arg) { num += arg; };
lambda(5);
```

A **functor** is any class that provides an implementation of operator().

They can create closures
 of "customized"
 functions!

```
class functor {
public:
    int operator() (int arg) const { // parameters and function body
        return num + arg;
    }
private:
    int num; // capture clause
};
int num = 0;
auto lambda = [&num] (int arg) { num += arg; };
lambda(5);
```

A **functor** is any class that provides an implementation of operator().

They can create closures
 of "customized"
 functions!

```
class functor {
public:
    int operator() (int arg) const { // parameters and function body
        return num + arg;
    }
private:
    int num; // capture clause
};
int num = 0;
auto lambda = [&num] (int arg) { num += arg; };
lambda(5);
```

Closure: a single instantiation of a functor object

A **functor** is any class that provides an implementation of operator().

- They can create closures of "customized" functions!
- Lambdas are just a reskin of functors!

```
class functor {
public:
    int operator() (int arg) const { // parameters and function body
        return num + arg;
    }
private:
    int num; // capture clause
};
int num = 0;
auto lambda = [&num] (int arg) { num += arg; };
lambda(5);
```

Closure: a single instantiation of a functor object

# Tying it all together

So far, we've talked about lambdas, functors, and function pointers.

# Tying it all together

So far, we've talked about lambdas, functors, and function pointers.

The STL has an overarching, standard function object!

std::function<return type(param types)> func;

# Tying it all together

So far, we've talked about lambdas, functors, and function pointers.

The STL has an overarching, standard function object!

std::function<return type(param types)> func;

Everything (lambdas, functors, function pointers) can be cast to a standard function!

# Tying it all together

So far, we've talked about lambdas, functors, and function pointers.

The STL has an overarching, standard function object!

std::function<return\_type(param\_types)> func;

Everything (lambdas, functors, function pointers) can be cast to a standard function!

Much bigger and more expensive than a function pointer or lambda!

Be careful using function pointers with classes, especially if you have a subclass of another class!

```
class Animal {
  // constructors and other methods go here!
  void speak() {
    std::cout << "I'm an animal!" << std::endl;
  } // private information and the rest of the class goes here!
}
class Dog : Animal { // this syntax tells us we're a subclass of Animal!
  // constructors and private information here!
  void speak() {
    std::cout << "I'm an animal!" << std::endl;
  } // private information and the rest of the class goes here!
}</pre>
```

What happens if we try to pass a Dog object to a function that expects an Animal?

```
void func(Animal* animal) {  // can take in any animal and make it speak!
  animal->speak();
}
int main() {
  Animal* myAnimal = new Animal;
  Dog* myDog = new Dog;
  func(myAnimal);
  func(myDog);
}
```

What happens if we try to pass a Dog object to a function that expects an Animal?

```
void func(Animal* animal) { // can take in any animal and make it speak!
    animal->speak();
}

int main() {
    Animal* myAnimal = new Animal;
    Dog* myDog = new Dog;
    func(myAnimal); \\ I'm an animal!
    func(myDog); \\ I'm an animal!
}
The function
will try to us
function! It of
overridden!
```

The function expects an Animal, so it will try to use the Animal speak function! It doesn't know it's been overridden!

### **Aside: Virtual Functions**

If you have a function that can take in a pointer to the superclass, it won't know to use the subclass's function!

### **Aside: Virtual Functions**

If you have a function that can take in a pointer to the superclass, it won't know to use the subclass's function!

The same issue happens if we create a superclass pointer to an existing subclass object.

### **Aside: Virtual Functions**

If you have a function that can take in a pointer to the superclass, it won't know to use the subclass's function!

The same issue happens if we create a superclass pointer to an existing subclass object.

To fix this, we can mark the overridden function as **virtual** in the header!

### **Aside: Virtual Functions**

If you have a function that can take in a pointer to the superclass, it won't know to use the subclass's function!

The same issue happens if we create a superclass pointer to an existing subclass object.

To fix this, we can mark the overridden function as **virtual** in the header!

Virtual functions are functions in the superclass we expect to be overridden later on.

Let's change Animal to have a virtual implementation of speak()!

```
class Animal {
// constructors and other methods go here!
    virtual void speak() {
        std::cout << "I'm an animal!" << std::endl;
    } // private information and the rest of the class goes here!
}
class Dog : Animal { // this syntax tells us we're a subclass of Animal!
// constructors and private information here!
    void speak() {
        std::cout << "I'm an animal!" << std::endl;
    } // private information and the rest of the class goes here!
}</pre>
```

Let's change Animal to have a virtual implementation of speak()!

```
void func(Animal* animal) { // can take in any animal and make it speak!
    animal->speak();
}

int main() {
    Animal* myAnimal = new Animal;
    Dog* myDog = new Dog;
    func(myAnimal); \\ I'm an animal!
    func(myDog); \\ I'm a dog!
}
```

Now calling speak() will use the correct subclass version!

```

With the algorithm library, we can...

#include <algorithm> :

With the algorithm library, we can...

check if a condition is true across any elements

#include <algorithm>:
any\_of all\_of none\_of

- check if a condition is true across any elements
- apply a function to all elements in a container

```
#include <algorithm>:
any_of all_of none_of
for_each
```

- check if a condition is true across any elements
- apply a function to all elements in a container
- search for specific elements or a range

```
#include <algorithm>:
any_of all_of none_of
    for_each
    find search
```

- check if a condition is true across any elements
- apply a function to all elements in a container
- search for specific elements or a range

```
#include <algorithm>:

- search for specific elements or a range
- copy, remove, add elements from one container to another

```
#include <algorithm>:
any_of all_of none_of
    for_each
    find search
    copy
```

#### What kind of algorithms?

With the algorithm library, we can...

- check if a condition is true across any elements
- apply a function to all elements in a container
- search for specific elements or a range
- copy, remove, add elements from one container to another
- and much, much more!

#include <algorithm>: all of none of any of for each find search copy

#### Look familiar?

```
count occurrences
```

```
template <typename InputIt, typename UniPred>
int count occurrences (InputIt begin, InputIt end, UniPred pred);
```

#### Look familiar?

```
count_occurrences
```

```
template <typename InputIt, typename UniPred>
int count_occurrences(InputIt begin, InputIt end, UniPred pred);
```

std::count\_if

```
template< class InputIt, class T >
typename iterator_traits<InputIt>::difference_type
    count( InputIt first, InputIt last, const T& value );
```

## **Algorithms**

All standard algorithms work on iterators.

- Efficient searching, sorting, complex data structure operations, smart pointers, and more are all there for you to use!
- Check out the documentation to get more information!

#### **Summary**

- Lambda functions are inline functions that let you pass outside variables in using capture clauses!
- Lambdas can be used to pass predicate function pointers to template functions for more generalizability.
- The STL implements tons of cool algorithms that we can use without rewriting them!

Next up: Operators!
